Page Fault (Bring the page from SM @ make its entry in the PMT)

n.

(1) Free space available in the memory -

OK

Bring that page, make its entry in PMT.

(2) No free space in memory -

Page Replacement

Remove a page from MM, delete its entry from PMT, Bring another page & make its entry in PMT.

### Algorithms of page replacement:-

1. First-in-first-out(FIFO)
2. Optimal Replacement
3. Least Recently Used(LRU)

1. **First-in-first-out(FIFO):** In this method, the oldest page present in the memory is selected for replacement.
2. **Optimal Replacement:-** This algorithm has lowest page fault rate for all algorithm of page replacement. This algorithm states that page which will not to be used for longest period of time i.e. **future knowledge of reference string is required.**
3. **Least Recently Used(LRU):-** In this algorithm, the page that has been not used for longest period of time is selected for replacement.

Bring another page & make its entry in PMT.

Handwritten notes showing a sequence of numbers (7, 0, 1, 2, 0, 3, 0, 4) and corresponding vertical columns of numbers (7, 0, 1, 2, 0, 3, 0, 4) with arrows indicating a process or transformation.

Q) Page fault 3 →

(1) 5    (2) 7    (3) 9

(4) 11

Process:-

At any time, during its execution, a process will be accessing only a small subset of logical address space. This subset of logical address space is called its current locality of its reference. The current locality keep on shifting.

# Page Replacement

Local Page Replacement

Replace a page from the same process whose next page is to bring in.

Global Page Repn.

Randomly remove any page from any process.

Problems  
Thrashing

→ ↑ page faults.

Problems

Overhead

## Thrashing:-

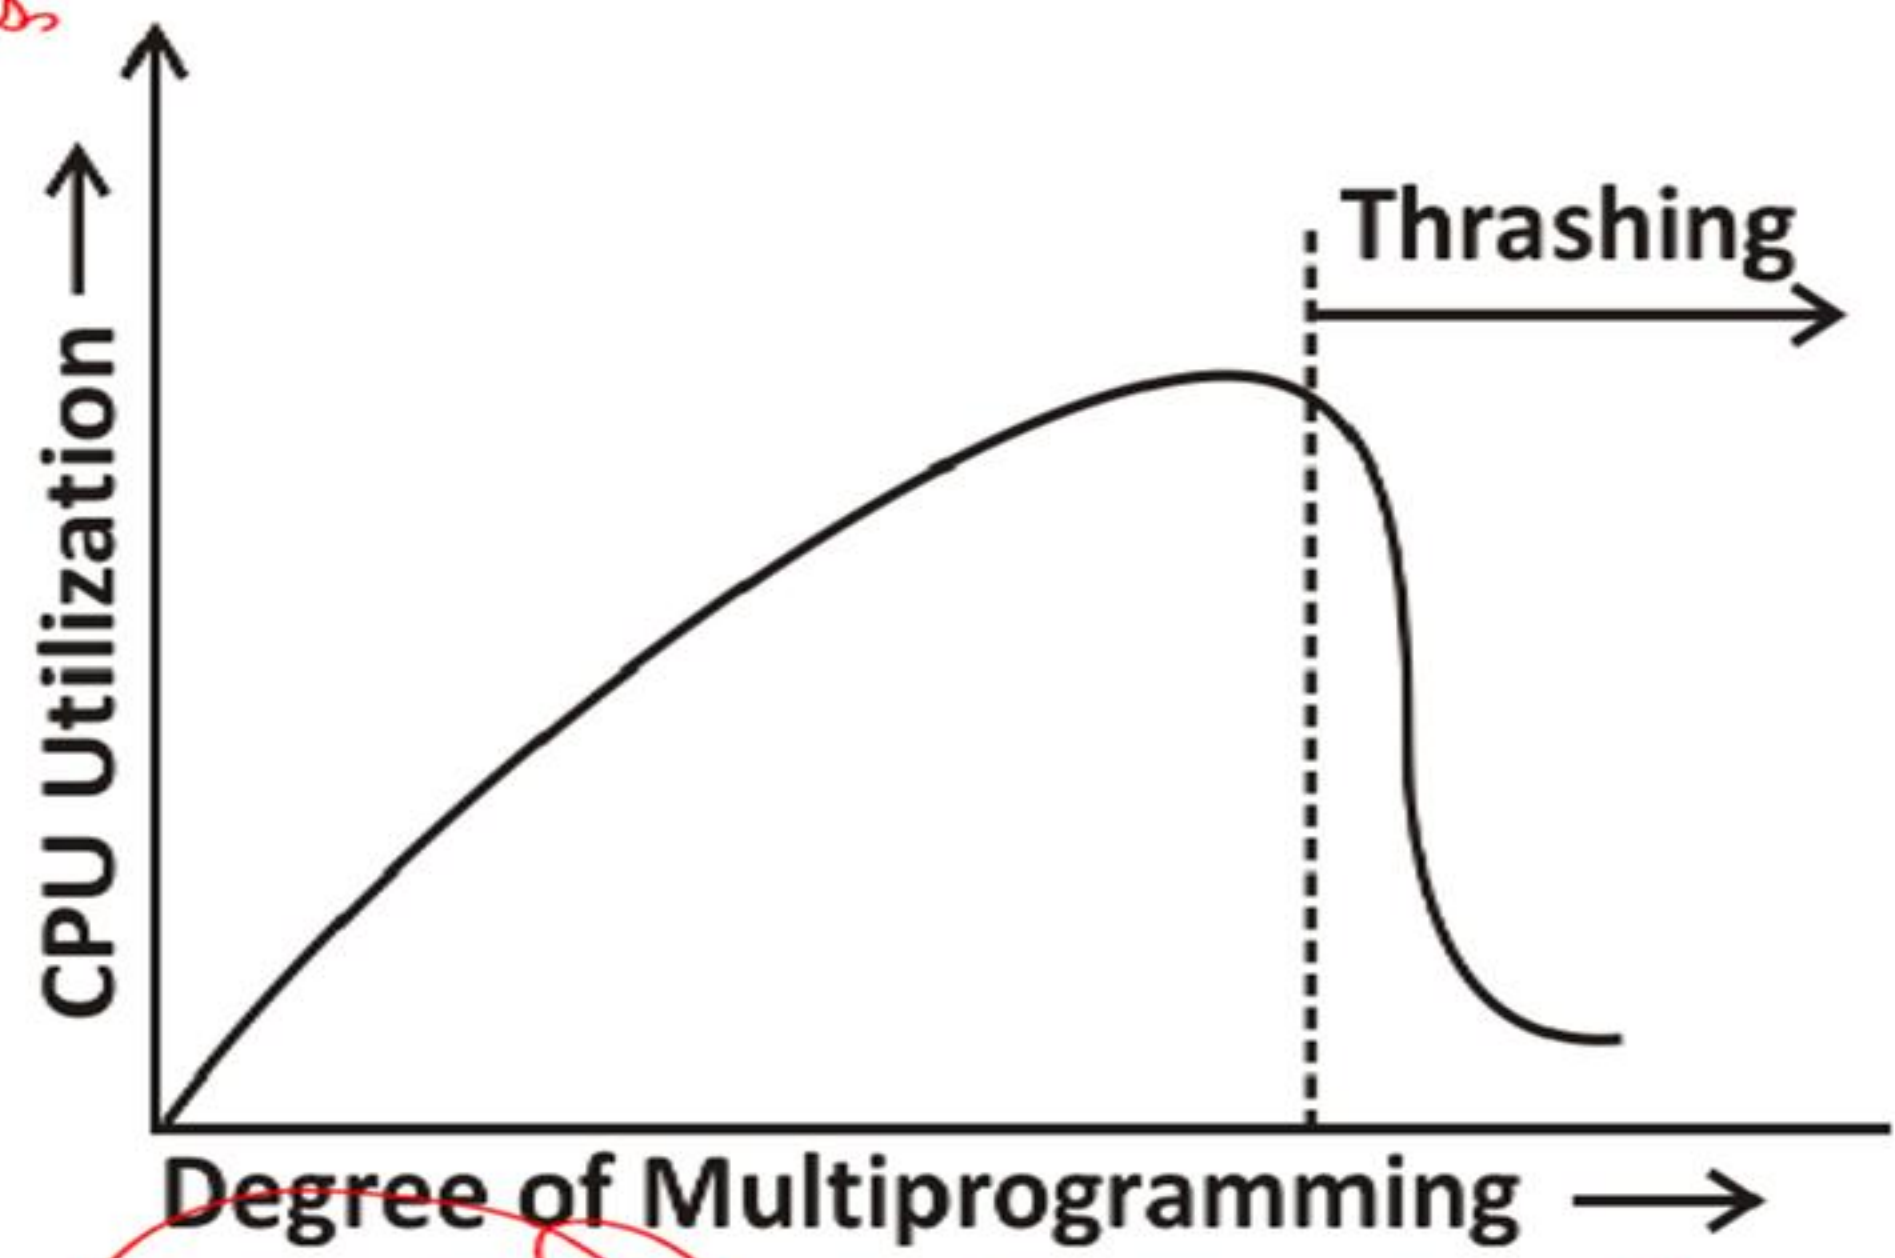

The phenomenon of moving pages from primary to secondary storage or vice-versa consumes a lot of computer's energy but accomplished very little useful results. This situation is called thrashing. A process is in thrashing, if it is spending more time is paging instead of their execution.

The CPU utilization is plotted against degree of multiprogramming. As degree of multiprogramming increases, CPU utilization goes on increasing although more slowly, until a maximum is reached. After this point degree of multiprogramming is increased then thrashing is occurred and CPU utilization drops sharply after this point.

Memory

Problem

limit the degree of multiprogramming.

COT

## Measures to avoid thrashing :-

To prevent from thrashing a strategy called as page-fault frequency (PFF) is used . since , thrashing has a high rate of page fault rate is too low , then the process has too many frames. We can establish upper and lowest bounds on the desired page fault rate. If the actual page fault rate exceeds the upper limit , we allocate that process to another frame. We remove a frame from that process if there is possibility arise for the rate of page fault falls below the lower limit . Thus we directly measure and control the page rate to prevent thrashing .
